Aggregate Functions

- used to summarize data
- returns a single Value
- Consolidate data
- It is a function that performs a calculation on multiple Rows in a specific Column and Returns a single Value or a single Value per group

SUM() - adds Values

AVG() - find the average

COUNT() - Count Rows

MAX() - Highest Value

MIN() - Smallest Value
or lowest

In Simple terms :- aggregate
= Summarize a group of Value
into one result

Oppra F	Beyannee F
Jalos M	Marle M
Elan M	Rofi M

2 females

4 Males

6 Learners

SELECT COUNT(*) AS CNT
FROM Students;

→ So Count(*) counts all the rows in the table
 ↳ If you want to know how many rows are in your table

GROUP BY

↳ Allows us to group our data by a specific category
 ↳ You group after aggregating

SELECT aggregate-function

SELECT aggregate-function(column) AS descriptor
FROM table-name
GROUP BY categorical-column;

Students

ID	Name	Gender
101	Rofhi	M
102	Elon	M
103	Opaca	F
104	Beyonce	F
105	Mark	M
106	Jeff	M

SELECT COUNT (ID) AS Num-learners,
Gender
FROM Student
GROUP BY Gender;

↓

N-learners	Gender
4	M
2	F

- So if the name of the column has a space we must put the name in single quotes

```
SELECT SUM('Total Amount')  
FROM workspace.default...
```

- You apply the group by function or statement when you have one column and a column which is aggregated.

- You apply the GROUP BY when one column is aggregate and the other column is not aggregated.

- So you group by the column that is not aggregated and categorical in the SELECT STATEMENT

```
SELECT Gender,  
       SUM('Total Amount') AS total-amount  
FROM  
GROUP BY Gender
```
